EFFECT OF ORGANIC AND INORGANIC  
FERTILIZERS ON NATURAL FOOD  
COMPOSITION AND PERFORMANCE OF  
AFRICAN CATFISH (*CLARIAS GARIEPINUS*)  
FRY PRODUCED UNDER ARTIFICIAL  
PROPAGATION

---

BY  
SEBASTIAN .S. MOSHA

# Introduction

- In Tanzania African catfish (*Clarias gariepinus*) is one of the common cultured sp.
- Its demand increases as;
  - food,
  - control over-population in tilapia ponds
  - bait for the Nile perch fishery.
- Catfish farming started during the colonial *era* but it has remained undeveloped.
  - Due to unavailability of quality feeds and seeds.
- Thus, most fish famers have driven to find alternatives such as fertilizers application.

Map of Tanzania

*C. gariepinus*

# Problem statement and Justification

- Rearing of *C. gariepinus* larvae to juveniles has proved to be challenging;
  - small size and lack of functional digestive system.
- Great losses are in the hatchery, as a fry weans from yolk absorption to exogenous feeding.
  - inability to accept large sized feeds and assimilate protein from dry formulated diets .
- *Artemia* constitutes an excellent starting food in larviculture of *Clarias gariepinus*.
  - High cost
  - not available in developing countries especially in rural areas

*C. gariepinus* larvae

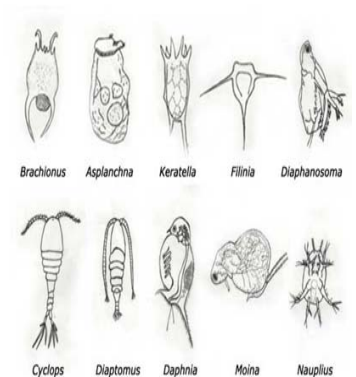

# Problem statement and Justification Cont...

- Provision of live feeds to fish larvae is important aspect;
  - supply nutrients and enzymes for digestion
- Fertilization in fish ponds/tanks is known worldwide to improve pond productivity;
  - promoting the growth of phytoplankton and increasing natural food available to fish
- Among fertilizers, chicken manure and di-ammonium phosphate (DAP) fertilizers were chosen;
  - very cheap and locally available to fish farmers.
  - contains a good combination of nitrogen and phosphorus in different proportions
  - increases the quantity of primary producers.

Phytoplankton

Zooplankton

# Problem statement and Justification Cont...

---

- A lot of progress has been made so far in aquaculture,
  - larvae rearing remains the bottleneck in *C. gariepinus* production.
- Therefore, the use of natural live feed at earlier stage of fry development seems to be one of the solutions to improve growth performance and survival.

Graduate Research Workshop  
May 5-6, 2016

# Objectives

---

## Objectives were to:

- Determine the abundance and diversity of different species of live food produced in tanks applied with chicken manure and DAP.
- Assess the growth performance of the catfish fry produced in tanks applied with chicken manure and DAP at different stocking densities.
- Evaluate the survival rate of the catfish fry produced in tanks applied with chicken manure and DAP at different stocking densities.
- Examine the water quality parameters in tanks applied with chicken manure and DAP at different fry stocking densities

# Materials and Methods

## Experiment 1: Determination of Abundance and Diversity of Natural Food.

- 9 concrete tanks (7m<sup>2</sup> each) were laid with 10cm of soil and filled with water to a depth of 0.8m.
- Three treatments:
  - 2kg of chicken manure, 42g of DAP fertilizer and no fertilizer (control) were randomly assigned to the tanks.
- Each treatment was replicated three times and all tanks were covered with nets

Concrete tanks with soil

Tanks covered with nets

# Materials and Methods Cont...

## Water sampling

- 1 week after fertilization water samples were collected with a 10L bucket from 4 points within each concrete tank.
- Placed into a plankton net with 20 $\mu$ m mesh size and left for about 20min.
- Concentrated sample from plankton net was transferred into 200 ml plastic bottles.
- Five drops of 70% alcohol were added to each sample to fix the organisms and taken to Faculty of Veterinary Medicine Laboratory
- Phytoplankton and Zooplankton abundance were calculated using the formulas as described by Greenberg *et al.* (1992) and Wetzel and Likens (1991).

Water filtering

Plankton count under microscope

# Materials and Methods Cont...

## Experiment 2: Determination of Growth and Survival of African Catfish Fry, *Clarias gariepinus*

- **Artificial propagation** was conducted according to de Graaf and Janssen (1996).
- A well distended, swollen abdomen female weighing 355g and a male weighing 350g were selected.
- A male weighing 344g was killed to get pituitary gland (0.09g)
  - ground in a porcelain mortar and mixed with salt solution (9 g of common salt/litre of water).
- A syringe was filled with the solution and female was injected intramuscularly to induce final maturation and ovulation of eggs.
- Stripping was carried out after 18 hrs of pituitary hormonal injection.

Brood stock selection

Egg stripping

# Materials and Methods Cont...

- The sperm obtained by killing a male and testes (1.6g) were rapidly cut into small pieces using a scissor into mortar
- The milt was pressed out with a pestle and mixed with eggs by stirring with a feather
- Eggs were spread out onto mosquito netting (mesh size 0.5 mm) placed in an incubator and eggs hatched after 27hrs at 28°C
- The hatchlings passed through the screen while shells remained on the screen.
- The hatchlings were collected and kept in an aquarium (0.6m<sup>2</sup>) placed in a dark places for 3 days.
- Larvae were fed 3g of formulated feed (55% crude protein) at an interval of every 2 hrs to satiation for a period of 4 weeks

Cutting of testes

Eggs fertilization

# Materials and Methods Cont...

## Fry stocking

- *C. gariepinus* fry (1 month old) with average weight of  $0.5\text{g} \pm 0.01\text{g}$  were randomly assigned to treatment tanks.
- Two stocking densities ( $5\text{fry}/\text{m}^2$  and  $10\text{fry}/\text{m}^2$ ) were used.
- Each stocking density was assigned at once and replicated three times.
- All 18 concrete tanks were covered with plastic nets to prevent predators.
- Fertilization was repeated after every week for a period of 2 months.
- During this period, all treatments were supplemented with the same diet formulated at 25% body weight per day

*C.gariepinus* fry

# Materials and Methods Cont...

## Data collection

- Weights of fry were measured every week at 08:00am by using analytical balance for all 2 months.
- The formula used in determine fry performance were according to Kang'ombe *et al.* (2006).

## Water quality

- Temperature ( $^{\circ}\text{C}$ ) and dissolved oxygen ( $\text{mg L}^{-1}$ ) were measured on daily basis (08:00-16:00hrs) using a multi-probe water checker.
- The pH was measured every day at 08:00hrs using pH meter.
- Ammonia and nitrite (ppm) were calculated once a week by using Salicylate Method and Diazotization Method respectively.

# Results

Table 1. Phytoplankton and zooplankton abundance (individuals/L) observed in tanks fertilized with different type of fertilizers (Mean  $\pm$  SE)

Treatment	Phytoplankton				Zooplankton		
	Chlorophyta	Cynophyta	Euglenophyta	Diatomae	Rotifers	Copepods	Cladocerans

# Conclusion and recommendation

---

- Zooplankton abundance were statistically higher in DAP fertilizer compared to other treatments.
- Zooplankton diversity were higher in chicken manure compared to other treatments.
- Growth performance parameters did not differ significantly between chicken manure and DAP fertilizer treatments across stocking densities.
- Survival rate of catfish fry was dependent on stocking density
  - High survival rate was recorded at low stocking density (5fry/m<sup>2</sup>) across all fertilizer types.
- Among water quality parameters dissolved oxygen during the afternoon and nitrite depended on fertilizer types.
- Catfish fry should be raised in DAP or chicken manure at low stocking density (5fry/m<sup>2</sup>) for better growth and survival in aquaculture practices.
